October is a consistent seasonal peak in two complete years (2024 and 2025). March 2026 stands out as an outlier: its Feb - Mar swing (+13.78%) is the largest month-over-month change in the dataset, well above the typical seasonal transition seen in 2024/2025.

Self Sufficiency by Month, 2024–2026

Month-over-Month Change in Self Sufficiency (%)

Year filter:
2026

February 2026 combined the lowest self-sufficiency of the year (86.3%) with the highest price (13.72 €/MWh). The following month saw self-sufficiency jump to 98.28% while price fell to 2.78 €/MWh, roughly an 80% drop, corresponding with the sharpest self-sufficiency swing in the 3-year dataset (see Trends). The same inverse pattern appears in parts of 2024 and 2025 but isn't consistent year-round, suggesting self-sufficiency is one contributing factor to price rather than the sole driver.

Self Sufficiency vs Price

Based on the 7-day rolling average trend, both consumption and production are forecast to stay roughly flat over the next 14 days, continuing the stable pattern seen through July. The widening confidence band reflects normal forecast uncertainty over a 2-week horizon, which projects near-term continuation of the recent pattern, not seasonal or weather-driven shifts.
